## Oligosaccharide (only)      11     6    0                1       0     4     22
```

```
# %s of structures in the PDB
Q1 <- (sum(PDB$X.ray)+sum(PDB$EM))/sum(PDB$Total)
Q2 <- (sum(PDB[1,7]))/sum(PDB$Total)
```

#Q1. 92.6% of structures in the PDB are solved by X-Ray and EM.

#Q2. 87.3% of structures in the BDP are proteins.

#Q3. There seem to be 1868 HIV-1 protease structures in the current PDB.

Visualizing the HIV-1 Protease Structure

#Q4. I believe that we see water as just one atom per molecule because the hydrogens are implied as their exact location cannot be precisely determined (minimum resolving size exceeds ~1A bond length).

#Q5. It isn't very clear as to where the binding site is at this point, but I identified OH308 as a possibility.

#Q6. I think the low B-value structures between the alpha helices and beta folds are the most likely to only take on that position and form those folds when the protein is dimerized.

Intro to Bio3D in R & Comparative Structure Analysis of Adenylate Kinase

```
# Organize Workspace
library(bio3d)

#Access online PDB file
pdb <- read.pdb("1hsg")
```

```
##   Note: Accessing on-line PDB file
```

```
print(pdb)
```

```
##
##  Call:  read.pdb(file = "1hsg")
##

#Q14. The black and colored lines are different in some places, but the same in others. I assume that the places where the black and color lines overlap is where the structure is conserved between the two conformations, and where they are divergent denotes the places where the two conformations differ the most (residues 40-60 and 125-150).
